## **INTRODUCTION**

### **A. OVERVIEW**

Recreational use of water with microbial contamination can pose health risks to swimmers and others. As a result, beach water quality is regulated to promote public health. In Massachusetts, bathing beach water quality is regulated by M.G.L. C. 111, § 5S and regulations cited as 105 CMR 445.000: Minimum Standards for Bathing Beaches (State Sanitary Code, Chapter VII; Appendix A). Local boards of health (LBH), the Metropolitan District Commission (MDC), the Barnstable County Department of Health and the Environment, and the Massachusetts Department of Environmental Management (DEM) conduct the vast majority of beach water sampling in Massachusetts. Most of the samples are analyzed at private labs, while some are analyzed at municipal facilities. There is no certification in Massachusetts for laboratories conducting these tests.

In 2000, the U.S. Congress enacted the Beaches Environmental Assessment and Coastal Health (BEACH) Act that amended the Federal Water Pollution Control Act (commonly referred to as the Clean Water Act, or CWA) to improve the quality of coastal recreational waters (Appendix B). The BEACH Act seeks to reduce the risk of disease to users of the Nation's marine recreational waters through the identification of high-risk beaches, identification and mitigation of sources of pollution, and notification/risk communication to the public. It also authorizes grants to eligible states to support these objectives.

In late 2001, the Massachusetts Department of Public Health (MDPH) was awarded funding from the United States Environmental Protection Agency (USEPA) that partially support Department efforts to develop an inventory of marine bathing beaches, compile monitoring data, and begin to conduct assessments of those beaches identified as high-risk. The MDPH Bureau of Health Quality Management, Division of Community Sanitation (DCS), conducted a survey of Massachusetts municipalities in order to develop an inventory of all public and semi-public marine and freshwater beaches. They also collected data from reporting local health departments and other agencies for the 2001 bathing season and provided these data to the MDPH Bureau of Environmental Health Assessment Environmental Toxicology Program (ETP). While the data were incomplete, this report presents the results and analysis of the available 2001 data from Massachusetts marine and freshwater bathing beaches.

## **II. BACKGROUND INFORMATION ON BEACH WATER QUALITY**

### **A. HEALTH EFFECTS FROM SWIMMING IN MARINE WATERS**

Several prospective and retrospective epidemiological studies conducted by USEPA (Cabelli, 1983; USEPA 1986; Cabelli, 1989) have concluded that swimming in polluted marine water poses health risks to swimmers. This conclusion is based on the observation that there is an increased rate of adverse health effects among swimmers

compared to non-swimmers in marine waters. Swimming in polluted marine water can lead to gastrointestinal symptoms (e.g., nausea, vomiting, diarrhea, abdominal pain), respiratory symptoms (e.g., sore throat, cough, chest cold, runny nose, sneezing), eye and ear symptoms (e.g., irritation, earache, itchiness), dermatological symptoms (e.g., skin rash, pruritis), and constitutional symptoms (e.g., fever, chills). The epidemiological studies suggest that swimmers may be exposed to pathogens (disease-causing microorganisms) while swimming. Pathogens in marine waters typically have a fecal source. Pathogens associated with human fecal matter (e.g., some strains of *Escherichia coli*) may be present in the water due to a variety of sources including but not limited to ocean disposal of sewage by boats, sewage treatment plant outfalls, illegal sewage hookups, and combined sewer overflows. Pathogens may be ingested or absorbed while swimming, thereby causing an increased risk of disease among swimmers relative to non-swimmers (Cabelli *et al.*, 1982; Cabelli, 1983; Cabelli, 1989; Coye and Goldoft, 1989; CDC, 1990-1996; Corbett *et al.*, 1993).

## **B. BEACH WATER QUALITY TESTING METHODS - MARINE**

The pathogens that cause swimming-associated disease are very difficult to measure directly. Furthermore, because of the wide variety of different pathogens that might be present in marine waters, measuring all possible pathogens is not practical for routine testing programs. Therefore, public health officials typically estimate the potential for pathogens to be present in the water by testing the water for a microorganism or a group of microorganisms whose life cycle(s) mimics that of specific pathogens but which are easier to measure than the pathogens themselves. Because they indicate when pathogens are likely to be present, these microorganisms or groups of microorganisms are called “indicators” (Cabelli, 1983).

In the United States, concern about pathogens in marine waters typically has been related to pathogens associated with fecal contamination (Cabelli, 1983). As a result, methods commonly used in this country test for an indication of the degree of fecal contamination of the water. The most accurate indicators of fecal contamination are specific microorganisms (e.g., *Escherichia coli*, *Streptococcus faecalis*, or *Clostridium perfringens*) that are present predominantly in human and animal feces (Cabelli, 1983). Testing for a single indicator species, however, can fail to detect the presence of fecal pathogens if that indicator species does not survive in the natural environment for as long as the fecal pathogens themselves do (NAS, 1977). Therefore, methods that test for groups of microorganisms, such as total coliforms, fecal coliforms, or Enterococci, are frequently used instead (Cabelli, 1983). These tests are usually easier and faster to perform than those that test for specific indicator species. In the case of Enterococci, they also strongly correlate with swimming-associated disease (USEPA, 1986). One disadvantage of using groups of microorganisms as indicators is that these tests can falsely predict the presence of fecal contamination if organisms that are not associated with fecal contamination are detected by the method (NAS, 1977; Cabelli, 1983).

As of the year 2000, Enterococci are the required indicator organisms for determining levels of contamination at marine bathing beaches in Massachusetts. In the past, total coliforms and fecal coliforms were used as indicators for marine bathing beaches. Some

beaches still do testing for total or fecal coliforms in addition to the mandated testing for Enterococci. Therefore, the methods for detecting and criteria set for total coliform, fecal coliform, and Enterococci are described below, even though Enterococci are the current indicator bacteria required by the Massachusetts State Sanitary Code.

### **1. Total Coliform Method**

The most general, but no longer recommended, testing method is the total coliform method. This method measures the number of bacteria in a water sample that will grow under certain laboratory conditions (Cabelli, 1983). A large number of different kinds of organisms are measured by this method, some of which are found exclusively in human and animal intestines (i.e., *Escherichia coli*) (Cabelli, 1983; USEPA, 1985). The advantages of this testing method are that it can be performed quickly and it is relatively sensitive to the presence of fecal contamination given the large number of species that it can detect. However, this method can falsely predict the presence of fecal pathogens because some of the species that are detected by the method (e.g., some species in the genus *Aeromonas*) are not found exclusively in human and animal feces (NAS, 1977; Cabelli, 1983). Furthermore, some waterborne pathogens (e.g., *Salmonella typhi*) and all viruses (e.g., Hepatitis A) are not measured by this method (NAS, 1977).

### **2. Fecal Coliform Method**

The fecal coliform test is similar to the total coliform test in that it measures the number of bacteria (including *Escherichia coli*) that can grow under certain laboratory conditions. However, the fecal coliform test only measures a subset of the species detected by the total coliform method. As a result, the fecal coliform test detects fewer organisms that are not associated with fecal contamination than the total coliform test, thereby reducing the chances of false-positive results. False positive results are still possible, however, because the fecal coliform method does detect some bacteria that have other sources besides human and animal feces (Cabelli, 1983). The fecal coliform method, like the total coliform method, can fail to detect waterborne pathogens in some cases because it does not detect all waterborne pathogens or viruses.

### **3. Enterococcus Method**

Similar to the total and fecal coliform methods, the Enterococcus method detects the number of bacteria that grow under certain laboratory conditions (USEPA, 1985). However, the Enterococcus method detects fewer total species than either the fecal or total coliform methods. The Enterococcus method measures the concentration of bacteria from a group of species within the *Streptococcus* genus, some of which (e.g., *Streptococcus faecalis*) are typically found in human and animal intestines (USEPA, 1985). Because some of the species that are detected by this method are not associated with fecal contamination (USEPA, 1985), this method can produce false-positive results, like the total and fecal coliform methods. In addition, some bacterial pathogens and all viruses are not detected by this method.

In 1986, the USEPA (1986) recommended that *Enterococcus* be used as an indicator of water quality at marine bathing beaches. This recommendation was based on studies by Cabelli (1983) at three locations (New York, NY; Boston, MA; and Lake Pontchartrain, LA). In these studies, Cabelli (1983) found that gastrointestinal symptoms reported by swimmers were strongly correlated with *Enterococcus* levels, but not with levels of total or fecal coliforms. Additionally, in 1997 EPA approved and adopted *Method 1600: Membrane Filter Test Method for Enterococci in Water*. This method enabled faster turnaround time for testing of *Enterococcus* as an indicator of water contamination, thereby making the method practical for local use.

## **C. HISTORICAL AND CURRENT WATER QUALITY CRITERIA - MARINE**

Water quality criteria are guidance concentrations that are used by public health officials to make decisions regarding the health risks associated with swimming. These criteria are typically expressed as the concentration of an indicator in the water above which there is an unacceptable risk for adverse health effects resulting from swimming. The concentrations of a microorganism in water are usually reported as the number of colony forming units (CFU) of indicators per 100 milliliters (ml) of water. For any given measurement of the indicator species in water, the actual health risk from swimming in that water will depend on what pathogens are present in the water. Therefore, to make a decision as to the actual health risk related to a particular beach, other factors in addition to water quality criteria for indicator species should be considered, such as recent rainfall patterns and the number of people who use the beach.

### **1. Total Coliform**

Formerly, the water quality criterion used by the Massachusetts Department of Public Health in the State Sanitary Code was based on the use of total coliforms. Specifically, the total coliform concentration could not exceed 1,000 CFU per 100 ml. After its establishment, this criterion was adopted by the Joint Committee of the American Public Health Association, the State Sanitary Engineers, and many states (Cabelli, 1983).

### **2. Fecal Coliform**

In 1968, fecal coliform replaced total coliform as the recommended indicator species for marine water quality, though fecal coliform is also no longer recommended under state guidelines. At that time, the National Technical Advisory Council (NTAC) of the Federal Water Pollution Control Administration established criteria for the geometric mean of the fecal coliform count over a 30-day period (for a minimum of five samples) at 200 CFU per 100 ml with no more than 10% of the samples exceeding 400 CFU per 100 ml. These values correlated with a level of risk of no more than 19 cases of acute gastrointestinal illness per 1,000 swimmers in marine waters. USEPA adopted this standard in 1976. By 1978, the majority of states and territories had adopted this standard as well (Cabelli, 1983; USEPA, 1986).

### **3. Enterococcus**

In 1986, USEPA published *Ambient Water Quality for Bacteria – 1986*. In this document, USEPA recommended Enterococcus instead of fecal or total coliforms as the indicator of marine water quality and provided a scientific rationale for its use. Enterococcus is currently the mandated indicator organism dictated by the Massachusetts State Sanitary Code (Appendix A).

The recommendation of the use of Enterococcus was based on studies by Cabelli (1983) that tested many different indicator organisms at several beaches in the United States to see which indicator organism correlated best with the incidence of acute gastrointestinal disease among swimmers. These studies showed that the concentration of Enterococcus in marine waters was more strongly correlated with the incidence of swimming-associated gastroenteritis than the concentrations of other indicators, including total and fecal coliforms. From these data, a relationship between the number of cases of swimming-associated disease and the Enterococcus concentration in the water was established. USEPA (1986) used this relationship to establish the criteria for Enterococcus in marine waters at 104 CFU per 100 ml for a single sample and 35 CFU per 100 ml for the geometric mean of at least five samples over a 30-day period. These criteria were set such that the expected incidence of gastrointestinal illness among swimmers would be the same as it had been for the previous USEPA water quality criteria for fecal coliform (i.e., 19 illnesses per 1000 swimmers at marine beaches). MDPH adopted this standard for the 2000 bathing season.

#### **D. HEALTH EFFECTS FROM SWIMMING IN FRESHWATER**

Several studies conducted by the USEPA and others (Dufour, 1984; USEPA, 1986; Cabelli, 1989; CDC, 1991-1996) have observed gastrointestinal symptoms (e.g. nausea, vomiting, diarrhea, abdominal pain) as a result of swimming in fresh waters. The results of these studies have suggested that swimmers may be exposed to pathogens while swimming in fresh waters. Pathogens associated with human fecal matter may be present in the fresh waters as a result of system failures in human sewage treatment facilities, or rainfall and resulting surface water runoff and other factors. Leachate from septic systems may be a potential source of microbiological contamination as well as animal wastes due to runoff that is exposed to domestic animal waste (e.g. wastes from dogs or farms). Swimmer-to-swimmer contamination is another potential source for microbiological contamination. Swimmers, bathers, waders, surfers, and others who come into full- or most-body contact may all contribute to contamination (California 1997).

#### **E. BEACH WATER QUALITY TESTING METHODS – FRESHWATER**

As indicated in the Massachusetts State Sanitary Code, the indicator organisms for freshwater bathing beaches are *E. coli* and Enterococcus based on recommendations by USEPA (Dufour, 1984; USEPA, 1986). The Enterococcus method has already been discussed (see Section III.C.3).

### **1. *E. coli* Method**

*Escherichia coli* (*E. coli*) is a species of bacteria that is found exclusively in human and animal intestines (USEPA, 1985). Certain strains of this species are enteric (i.e., intestinal) pathogens (NAS, 1977). While both the total and fecal coliform methods can detect *E. coli* as part of a group of organisms, the *E. coli* method tests specifically for the presence or absence of this particular species. Because *E. coli* is exclusively found in human and animal intestines, this method is a very sensitive indicator of fecal contamination for freshwater beaches (USEPA, 1985).

## **F. CURRENT WATER QUALITY CRITERIA – FRESHWATER**

As noted in Section III. C., for any given measurement of the indicator species in water, the actual health risk from swimming in that water will depend on what pathogens are present in the water. Therefore, to make a decision regarding the health risk related to a particular beach, other factors must be considered in addition to water quality criteria for indicator species, such as recent rainfall patterns and the number people who use the beach.

### **1. *E. coli***

For freshwater, no single *E. coli* sample shall exceed 235 CFU per 100 ml and the geometric mean of the most recent five *E. coli* samples within the same bathing season shall not exceed 126 CFU per 100 ml. These are the criteria established by the Massachusetts State Sanitary Code (Appendix A).

### **2. Enterococcus**

For freshwater, no single Enterococcus sample shall exceed 61 CFU per 100 ml and the geometric mean of the most recent five Enterococci samples within the same bathing season shall not exceed 33 CFU per 100 ml. These are the criteria established by the Massachusetts State Sanitary Code (Appendix A).

Both *E. coli* and enterococcus standards are based on studies (Dufour, 1984; USEPA, 1986) that showed a strong correlation between levels of *E. coli* and Enterococcus and rates of swimmer-associated gastrointestinal disease in freshwaters. The values are set to a level of risk of no more than eight cases of acute gastrointestinal disease per 1,000 swimmers in freshwater beaches.

## **III. METHODS**

### **A. DESCRIPTION**

Local boards of health from the cities and towns in Massachusetts that have public and semi-public bathing beaches are required to submit to MDPH beach field data and lab results for bathing beaches under their jurisdiction. The data collected by each

community were based on a field data collection form from the MDPH Bureau of Health Quality Management, Division of Community Sanitation (DCS). Sample collection and testing were required to be in compliance with the *Standard Methods for the Examination of Water and Waste Water* of the American Public Health Association or as approved by the USEPA. This form will be amended in the future to accommodate more information and be used consistently across the state. The information collected varied from town to town, but the basic variables included:

- Name of beach
- Town where beach is located
- Sample identification number
- Date of sample collection
- Time of sample collection
- Weather condition at time of sample collection
- Air temperature
- Wind direction
- Time of last high tide (if applicable)
- Amount of most recent rainfall
- Number of days from end of most recent rainfall to sample collection day
- Sampling agency (i.e., local board of health, MDC, DEM, outside lab, other)
- Known pollution sources (i.e., boats, wildlife, septic systems, outflow pipes, streams)
- Beach type (i.e., marine or freshwater)
- Bather density (i.e., number of people in the water)
- Water temperature
- Water clarity
- Water salinity
- Observations (i.e., trash, sludge deposits, oils, algae, fish die-off, jellyfish, birds)
- Indicator (i.e., Enterococcus for marine, Enterococcus or *E. Coli* for freshwater; note, some towns still use the fecal coliform and total coliform indicators which are not in compliance with the Massachusetts State Sanitation Code)
- Indicator level in colony forming units (CFU) of bacteria per 100 ml of water
- Violation (i.e., indicator levels equal to or greater than 104 CFU / 100 ml for Enterococcus in marine waters, 61 CFU / 100 ml for Enterococcus in fresh waters, or 235 CFU / 100 ml for *E. coli* in fresh waters)
- Comments

## **B. LIMITATIONS**

The beach inventory database and monitoring data are subject to certain limitations. First, the database is only as complete as the data received. For example, during the 2001 bathing season, each city/town used different monitoring techniques. Therefore, the comprehensiveness of the data varies from town to town. The development of the beach inventory and GIS databases should help standardize data reporting across the state.

Second, the accuracy of the data depends on proper sample collecting and testing techniques.

Third, the data are indicator-, not pathogen-, specific. As a result, the data only suggest a potential for the presence of pathogens that can cause human disease. The presence or absence of specific pathogens is not assayed. The use of indicators implies that water meeting the criteria may harbor disease-causing microorganisms and also that water considered unsafe may not carry any disease-causing microorganisms (e.g., Polo *et al.*, 1998; Moore *et al.*, 2001; Prieto *et al.*, 2001; Schindler, 2001). This is an inherent limitation of using indicators as a test of water quality.

Fourth, the criteria developed for each indicator are set at an acceptable level of risk of an adverse health effect, not at a no-risk level. Therefore, levels of indicators considered safe by the guidelines do not imply freedom from risk of adverse health effects for the total population at risk.

Finally, acceptable levels of risk are typically determined by the incidence of gastrointestinal symptoms among swimmers compared to that for non-swimmers. It should be noted, however, that pathogens found in marine and freshwater can cause other symptoms, including respiratory, dermatologic, ophthalmologic, and constitutional. These symptoms are generally not taken into account in determining criteria for the different indicator species.

## **IV. RESULTS**

During the 2001 bathing season, the majority of Massachusetts cities/towns with public and semi-public marine and/or freshwater beaches sent water quality data to MDPH. These data were entered into tabular and Geographic Information System (GIS) databases in order to build an inventory of bathing beaches in Massachusetts and to allow for storage and analysis of field data and testing results. After the data were entered into the computer, the database was verified by someone other than the person who did the data entry. Ten percent of the records entered into the database were checked for quality assurance/quality control, and two percent of these records were found to have errors, which were subsequently corrected.

In total, MDPH received water quality data from 179 Massachusetts cities and towns, representing 879 public and semi-public marine and freshwater beaches and 12,851 water samples. Private marine or private freshwater bathing beaches are not part of this report.

Summaries and analyses of the marine and freshwater bathing beach data are presented in Tables 1 – 18 and Figures 1 – 15. The data are divided by type of beach (marine vs. freshwater) to allow easy comparison to earlier reports that analyzed marine bathing beaches only (e.g., MDPH/BEHA Environmental Toxicology Program (ETP) 1997) and to accommodate the different testing criteria for the two types of beaches (see Background section). The data are analyzed according to type of beach, presence or absence of data, bather density, pollution source, bacterial indicator, frequency of testing, organization that performed testing, violations based on current Massachusetts criteria, and beach postings. Data are grouped either according to town/city, beach, or water

sample, depending on ease of understanding and interpreting the results. For example, bather density at a given beach changes during the day and season, so it makes sense to express these data in terms of water sample (i.e., at times when samples were collected). Alternatively, testing frequency only makes sense in terms of a given beach for a particular indicator. The data are presented in tabular (Tables 1- 18), pie graph (Figures 1 – 11), and map (Figures 12 – 15) forms.

## **V. DISCUSSION**

### **A. MARINE BEACHES**

During the 2001 bathing season, a total of 58 of the 59 Massachusetts coastal cities/towns with public and semi-public marine bathing beaches submitted beach-monitoring data to MDPH. Analysis of these data is provided in Tables 1 - 18 and Figures 1 - 15.

Tables 1 – 3 and Figures 1 - 2 indicate the number of coastal cities/towns with and without public and semi-public marine bathing beaches, broken down by those that reported data (83% of all coastal towns) and those that did not (3% of all coastal towns). The remaining 14% of coastal cities/towns do not have public marine bathing beaches. Table 4 indicates the total number of coastal cities/towns (58), marine beaches (448), and water samples (7,200) included in the 2001 marine bathing beach database. Note that, in contrast to the 1997 Report (MDPH/BEHA/ETP 1997), the number of beaches that were not tested was not included here, as this number could not be determined from the data provided. The total number of marine beaches for which data were available for inclusion in the 1997 report was 325.

Table 5 and Figure 4 provide approximate bather density at public and semi-public marine bathing beaches at the time that samples were taken. It is important to note that almost half (48%) of the samples were taken without noting bather density, making interpretation difficult. However, the available data indicate that about 80% of marine water sampling occurred at a time when only 0-10 people were using the beach. This low bather density might reflect typical beach usage, or indicate that water sampling was not done during peak usage.

Tables 6 – 7 indicate open or obvious sources of pollution at times when samples were taken. Again, these data are largely incomplete, with 99.5% of the reports not indicating whether a pollution source was present (i.e., 99.5% of respondents left this section blank rather than indicating “yes” or “no” with regard to a potential pollution source). Furthermore, for the 0.5% of reports that indicated a pollution source, the majority (69%) indicated “other” rather than identifying a likely source. The little information available from the surveys indicate outflow pipe and septic systems as the most frequently reported sources of pollution. For this reason methods to collect and report complete/accurate information on potential sources of pollution in the beach areas should be further explored.

Tables 8 –9 and Figure 6 summarize bacterial indicator data. Table 8 reports the bacterial indicator for each of the 7,200 marine water samples collected in the 2001 bathing beach season, while Table 9 groups the bacterial indicator by beach. These data indicate that *Enterococcus* was the indicator used at all public marine bathing beaches that reported water quality data at some time during the 2001 bathing season. However, some of the water samples (about 2%) were inappropriately analyzed for fecal or total coliform, not *Enterococcus*. Overall, five percent of the beaches tested not only for *Enterococcus* but also for *E. coli*, fecal coliform, or total coliform at some point during the 2001 bathing season.

Table 10 and Figure 8 indicate testing frequency of public and semi-public marine bathing beaches in 2001, with the majority of the beaches (93%) tested on a weekly or more frequent basis. Table 11 notes the testing agency that performed the water quality sampling, with the local health department (59%), MDC (20%), and outside laboratories (20%) performing the vast majority of the sampling.

Tables 12 – 14 and Figure 10 provide data regarding water samples that exceeded the Massachusetts single-count criterion (104 CFU per 100 ml for *Enterococcus*). Table 12 groups the data by water sample (6% (n=444), of the 7,200 water samples exceeded the single-count criterion), Table 13 by beach (35% (n=158), of the 448 public and semi-public marine bathing beaches had at least one sample exceeding the single-count criterion), and Table 14 by indicator. A more detailed evaluation of beaches with more than one exceedance will be prepared in the next annual report (based on 2002 data).

Note that 2% (n=166), of the water samples did not report an indicator, reported an indicator but not a level, or reported an indicator that does not have current Massachusetts guidelines. These samples were placed in an indeterminant category, indicating that the total number of exceedances may be an underestimate of the number of water samples with a potential for bacterial contamination.

Table 15 relates beach postings to exceedances. This table indicates that there are far fewer postings than exceedances. This discrepancy could result from an incomplete database of beach postings due to a lack of reporting by beach communities, or from the possibility that many violations that did not result in postings. Clearly, the latter possibility highlights the need for tighter linkage between exceedances and beach postings.

Table 16 lists the individual coastal cities/towns and beaches included in the database, with separate entries for each bacterial indicator used, as well as number of tests, violations, and non-violations for each. Table 18 lists all Massachusetts towns, indicating type of beach and presence or absence of data. Figures 12 and 14 provide data of city/town and exceedances, respectively, in map form.

## **B. FRESHWATER BEACHES**

During the 2001 bathing season, a total of 145 of the 175 Massachusetts cities and towns with public and semi-public freshwater bathing beaches submitted beach monitoring data to MDPH. Analysis of these data is provided in Tables 1 - 18 and Figures 1 - 15.

Tables 1 – 3 and Figures 1 and 3 indicate the number of cities/towns with and without public and semi-public freshwater bathing beaches. About half of Massachusetts cities/towns have freshwater bathing beaches. Of these, 82% reported data. Table 4 indicates the total number of cities/towns (145), public and semi-public freshwater bathing beaches (431), and water samples (5,651) included in the 2001 freshwater bathing beach database.

Table 5 and Figure 5 provide approximate bather density at public and semi-public freshwater bathing beaches at the time that samples were taken. It is important to note that more than half (57%) of the samples were taken without noting bather density, making interpretation difficult. However, the available data indicate that the majority of samples (70%) were taken at times when only 0-10 people were using the beach. Like that for marine beaches, this observation could reflect typical beach usage or that sampling usually occurred at times of non-peak usage.

Tables 6 – 7 indicate open or obvious sources of pollution at times when samples were taken. Again, these data are largely incomplete, with 99.9% of the samples not indicating whether or not a pollution source was present (i.e., 99.9% of respondents left this section blank rather than indicating “yes” or “no” with regard to a potential pollution source). The five reports that did report an open or obvious source of pollution all indicated septic systems as the pollution source. Better ways to collect and report information on potential sources of pollution in the beach areas are warranted.

Tables 8 –9 and Figure 7 summarize bacterial indicator data. Table 8 reports the bacterial indicator for each of the 5,651 water samples collected in the 2001 bathing beach season, while Table 9 groups the bacterial indicator by beach. These data indicate that about 90% of the freshwater beach samples were analyzed using *Enterococcus* or *E. coli*, as recommended by state guidelines. When considered from the point of view of beach rather than water sample (Table 9), 94.2% of Massachusetts freshwater beaches use at least *Enterococcus* or *E. coli* at some point during the 2001 bathing season (some of these beaches may use additional indicators as well).

Table 10 and Figure 9 indicate testing frequency of public and semi-public freshwater bathing beaches in 2001, with 73% of the beaches (403 of 556) tested on a weekly or more frequent basis. Table 11 notes the testing agency that performed the water quality sampling, with the local health departments (45%), private labs (34%), and Department of Environmental Protection (16%) performing the majority of sampling.

Tables 12 – 14 and Figure 11 provide data regarding water samples that exceeded Massachusetts single-count criteria (61 CFU per 100 ml for *Enterococcus*, 235 CFU per 100 ml for *E. coli*). Table 12 shows that 6% (n= 336), of the 5,651 water samples

exceeded the single-count criteria. Table 13 shows that 30% (n=130), of the 431 freshwater bathing beaches had at least one sample exceeding the single-count criteria. A more detailed evaluation of beaches with more than one exceedance will be prepared in the next annual report (based on 2002 data).

Note that 12% (n=704), of the water samples either did not report an indicator, reported an indicator but not a level, or reported an indicator that does not have current Massachusetts guidelines. These samples were placed in an indeterminant category, indicating that the total number of violations may be an underestimate of the number of samples with violations.

Table 15 relates beach postings to violations. This table indicates that there are far fewer postings than violations. Only 27% of the violations based on *Enterococcus* and 26% of the violations based on *E. coli* resulted in reported postings. This discrepancy could result from lack of reporting by beach communities, or many violations that did not result in postings. Both of these possibilities warrant further evaluation.

Table 17 lists the individual Massachusetts cities/towns and beaches included in the database, with separate entries for each bacterial indicator used, as well as number of tests, violations, and non-violations for each. Table 18 lists all Massachusetts towns, indicating type of beach and presence or absence of data. Figures 13 and 15 provide data of city/town and violation, respectively, in map form.

## **VI. FUTURE ACTIVITIES**

### **A. STANDARDIZED REPORTING FORM**

In order to be able to effectively compare data from all beaches from year to year, it will be necessary for all Massachusetts cities and towns with public and semi-public bathing beaches to use a standard reporting form when submitting beach monitoring data to MDPH. The MDPH Bureau of Health Quality Management, Division of Community Sanitation, has developed a standard reporting form that is readily available on the web. All cities/towns with public and semi-public bathing beaches will use this form to submit beach-monitoring data to MDPH. If data can be submitted electronically, compiling and summarizing the data will be easier and more timely. In addition, electronically reporting postings will expediate postings on the MDPH/BHQM web site, (see section D).

### **B. GEOGRAPHIC INFORMATION SYSTEM (GIS)**

A geographical information system (GIS) beach inventory database showing the location of all the public and semi-public bathing beaches in Massachusetts is currently being developed by MDPH/BEHA ETP based on the beach inventory database. Eventually each beach in the GIS will be assigned a unique identification number that will include codes for the region, city/town, type of beach, and beach name. This number will be provided on future field data collection forms that will be distributed to each city/town to

facilitate data entry into the inventory database and to facilitate linking data for each beach to the GIS beach inventory layer.

### **C. TIER SYSTEM FOR BEACH CLASSIFICATION**

Using data gathered from the local boards of health in cities/towns with public and semi-public bathing beaches, MDPH will set up a tier system for classifying beaches. Developing a tier system will help support variance requests under 105 CMR 445.000. The tier system is also a requirement specified by EPA in awarding funds under the BEACHES ACT.

The three tiered categories will be high, medium and low priority beaches assigned according to specific criteria which may include amount of rainfall in the area, number of known and potential pollution sources, bather density, occurrence of malfunctioning septic systems in the area, public comment, and history of violations for levels of indicator organisms.

A “high” priority beach will receive the most frequent water quality sampling and analysis. Such a beach might be one with high bather volume, high frequency or percentage of violations, problematic sources of pollution, or a combination of these factors. A “medium” priority beach will have less frequent sampling but will still be required to meet water quality standards. Beaches that are tiered “medium” will have any of the factors listed for “high” priority beaches but with less frequency or intensity of any of the three criteria. A “low” priority beach will indicate that sources of pathogens are rare or that few people swim in the water. In this case, water quality monitoring might be limited to an annual survey or conducted only on public complaint, or the local health department might apply for a testing variance. Data from the 2002 bathing season will be analyzed to identify a tier for each beach and to determine if the tier classification system is effective.

### **D. REPORTING BEACH POSTINGS ON THE WORLD WIDE WEB**

MDPH Bureau of Health Quality Management, DCS, is in the process of developing a system that would allow beach postings to be reported on the web and updated regularly. This will enable beach patrons to easily determine which beaches are open on any particular day/week and choose a suitable beach. It will also enable the public to see which beaches are posted and for what reason, and to keep track of a beach and its history of postings.

## **VII. SUMMARY**

This report summarizes beach monitoring and testing data from Massachusetts public and semi-public marine and freshwater bathing beaches in the 2001 season. In total, 179 communities, 879 beaches, and 12,851 water samples were available for analysis. The report highlights the need for a consistent sanitary survey protocol, electronic submission of data, use of appropriate bacterial indicators, and tighter links between violations and beach postings. A beach monitoring inventory and GIS database were created to

organize and analyze the data, as well as to provide a template for future monitoring efforts.

## **VIII. ACKNOWLEDGMENTS**

This study would not have been possible without the efforts and cooperation of the local and county health departments in the Massachusetts cities and towns that are included here. MDPH also received much assistance from many local and regional organizations, including the MDC. Finally, we are grateful to the USEPA for providing financial support for this effort.

## X. TABLES

**Table 1:** All Massachusetts cities and towns grouped by the presence and/or absence of marine and freshwater public and semi-public bathing beaches.

Type of city/town	Number (#)	Percentage (%)
Marine beach only	35	10
Freshwater beach only	151	43
Marine and freshwater beaches	24	7
No beaches	141	40
Total	351	100

**Table 2:** All Massachusetts cities and towns grouped according to the presence or absence of data for marine or freshwater public and semi-public bathing beaches.

Type of city/town	Number (#)	Percentage (%)
Marine or freshwater beach, with data <sup>1</sup>	179	51
Marine or freshwater beach, without data	31	9
No beaches	141	40
Total	351	100

1. The data included in this report were submitted from Massachusetts cities/towns through 6/30/02 for the 2001 bathing season.

**Table 3:** Water quality testing at marine and freshwater public and semi-public bathing beaches in Massachusetts, grouped by town, for the years 2001, 1996, and 1995.

<b>Coastal cities/towns</b>						
Type of city/town	2001		1996		1995	
	#	%	#	%	#	%
Coastal cities/towns with marine bathing beaches	59 <sup>1</sup>	86	60 <sup>1</sup>	86	60	86
Coastal cities/towns with marine bathing beaches for which data were obtained	58	83	53	76	52	74
Coastal cities/towns with marine bathing beaches for which no data were obtained	2	3	7	10	8	12
Coastal cities/towns without marine bathing beaches	10	14	10	14	10	14
Total number of coastal cities/towns	70	100	70	100	70	100
<b>All cities/towns</b>						
Type of city/town	2001		1996		1995	
	#	%	#	%	#	%
Cities/towns with freshwater bathing Beaches	175	50	N/A	N/A	N/A	N/A
Cities/towns with freshwater bathing beaches for which data were obtained	145	41	N/A	N/A	N/A	N/A
Cities/towns with freshwater bathing beaches for which no data were obtained	30	9	N/A	N/A	N/A	N/A
Cities/towns without freshwater bathing beaches	176	50	N/A	N/A	N/A	N/A
Total number of cities/towns	351	100	N/A	N/A	N/A	N/A

1. The 59 coastal cities/towns with public and semi-public marine beaches in this report differs from the 60 in the 1996 report by the inclusion here of Somerset (mistakenly omitted in the 1996 report), the omission of Pembroke (mistakenly included as marine in the 1996 report), and the omission of Rowley (included in the 1996 report as having public or semi-public marine beaches, when in fact it does not).

**Table 4:** Water quality testing at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, grouped by city/town, beach, and sample.

Type of city/town	# cities/towns (total)	# cities/towns with data	# beaches <sup>1</sup>	# samples
Cities/towns with marine bathing beaches	59	58	448 <sup>2</sup>	7,200
Cities/towns with freshwater bathing beaches	175	145	431	5,651
Total	210 <sup>4</sup>	179 <sup>3,4</sup>	879 <sup>3</sup>	12,851 <sup>3</sup>

1. Note that this table does not include the number of beaches that were not tested, as data were not compiled to accurately determine this number.
2. This number differs from that in the 1996 report, which indicated a total of 325 marine public and semi-public bathing beaches (296 with data and 29 without data).
3. These numbers represent the total number of cities/towns, beaches, and samples, respectively, for which there are data in 2001.
4. The total number of cities/towns is less than the sum of the number of cities/towns with marine beaches and those with freshwater beaches because there are towns that have both marine and freshwater bathing beaches (24 in total; see Table 1).

**Table 5:** Bather density at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, at times when samples were taken.

<b>Marine beaches</b>		
Bather Density (# people)	#	%
0-10	2,921	41
10-20	315	4
20-50	297	4
>50	209	3
Not indicated	3,458	48
Total	7,200	100
<b>Freshwater beaches</b>		
Bather Density (# people)	#	%
0-10	2,000	35
10-20	191	4
20-50	144	3
>50	71	1
Not indicated	3,245	57
Total	5,651	100

**Table 6:** Reported existence of open or obvious sources of pollution that might affect the water quality at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001.

<b>Marine beaches</b>		
Pollution source	#	%
Yes	36	0.5
No	0	0
Not indicated	7,164	99.5
Total	7,200	100
<b>Freshwater beaches</b>		
Pollution source	#	%
Yes	5	0.1
No	0	0
Not indicated	5,646	99.9
Total	5,651	100

**Table 7:** Reported sources of pollution for marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001 for which a pollution source was specified.

<b>Marine beaches</b>		
Sources	#	%
Boat	0	0
Wildlife	0	0
Septic System	2	6
Outflow pipe	9	25
Stream	0	0
Other	25	69
Total	36	100
<b>Freshwater beaches</b>		
Sources	#	%
Boat	0	0
Wildlife	0	0
Septic System	0	0
Outflow pipe	5	100
Stream	0	0
Other	0	0
Total	5	100

**Table 8:** Water quality bacterial indicators used to test marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, grouped by sample.

<b>Marine beaches</b>		
Indicator <sup>1</sup>	#	%
Enterococcus	7,081	98.3
<i>E. coli</i>	1	0.1
Fecal coliform	83	1.2
Total coliform	35	0.5
Fecal streptococcus	0	0.0
Not indicated	0	0.0
Total	7,200	100.0
<b>Freshwater beaches</b>		
Indicator <sup>2</sup>	#	%
Enterococcus	1,211	21
<i>E. coli</i>	3,822	68
Fecal coliform	173	3
Total coliform	360	6
Fecal streptococcus	14	0.3
Not indicated	71	1.7
Total	5,651	100

1. Massachusetts state guidelines indicate that Enterococcus be used to test marine beaches for potential bacterial contamination.

2. Massachusetts state guidelines indicate that Enterococcus or *E. coli* be used to test freshwater beaches for potential bacterial contamination.

**Table 9:** Water quality bacterial indicators or combinations of indicators used to test marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, grouped by beach.

<b>Marine beaches</b>		
Indicator(s)	#	%
Enterococcus only	420	95
<i>E. coli</i> only	0	0
Fecal coliform only	0	0
Total coliform only	0	0
Enterococcus and <i>E. coli</i>	1	0.2
Enterococcus and Fecal coliform	20	3.3
Enterococcus and Total coliform	5	1.1
Enterococcus, Fecal coliform, and Total coliform	2	0.2
Not indicated	0	0
Total	448	100
<b>Freshwater beaches</b>		
Indicator(s)	#	%
Enterococcus only	45	10
<i>E. coli</i> only	265	61
Fecal coliform only	0	0
Total coliform only	15	3
Enterococcus and <i>E. coli</i>	42	10
Enterococcus and Fecal coliform	0	0
Enterococcus and Total coliform	4	1
<i>E. coli</i> and Fecal coliform	8	2
<i>E. coli</i> and Total coliform	16	4
<i>E. coli</i> and Fecal streptococcus	3	1
Fecal coliform and total coliform	2	0.5
Enterococcus, <i>E. coli</i> , and Fecal coliform	4	1
Enterococcus, <i>E. coli</i> , and Total coliform	12	3
<i>E. coli</i> , Fecal coliform, and Total coliform	6	1
<i>E. coli</i> , Fecal coliform, Total coliform, and Fecal streptococcus	1	0.2
Fecal coliform and Fecal streptococcus	1	0.2
Not indicated	9	2
Total	431	100

1. Each of the rows in this table is independent of the others (e.g., the number of beaches tested for Enterococcus and *E. coli* together is not included in the number of beaches tested for Enterococcus only).
2. Beaches that use multiple indicators usually do not use them on a consistent basis (e.g., water samples on a given date are tested with one indicator, while those tested on a different date are tested with another indicator).

**Table 10:** Frequency of water quality testing at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, grouped by beach and indicator.

<b>Marine beaches</b>		
Test frequency	#	%
Daily	4	1
Twice per week	10	2
Weekly	432	90
Twice per month	4	1
Monthly	4	1
Three times	0	0
Two times	3	1
One time	21	4
Total	478 <sup>1</sup>	100
<b>Freshwater beaches</b>		
Test frequency	#	%
Daily	2	0.5
Twice per week	13	2
Weekly	388	70
Twice per month	29	5
Monthly	46	8
Three times	2	0.5
Two times	14	3
One time	62	11
Total	556 <sup>1</sup>	100

1. The total number represents the number of beaches, with some beaches represented several times if multiple indicators were used (see Tables 16, 17, and 18).

**Table 11:** Groups, agencies, or individuals who performed water sampling at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001.

<b>Marine beaches</b>		
Testing organization	#	%
Local Health Department	4,242	59
Metropolitan District Commission (MDC)	1,414	20
Department of Environmental Management	72	1
Outside lab	1,472	20
Other	0	0
Total	7,200	100
<b>Freshwater beaches</b>		
Testing organization	#	%
Local Health Department	2,542	45
Metropolitan District Commission (MDC)	281	5
Department of Environmental Management	902	16
Outside lab	1,925	34
Other	1	0
Total	5,651	100

**Table 12:** The number of samples in which the measured Enterococcus concentration (marine beaches) or Enterococcus or *E. coli* concentration (freshwater beaches) exceeded their respective water quality criteria at public and semi-public bathing beaches in Massachusetts in 2001.

<b>Marine beaches</b>		
Concentration	#	%
Violation <sup>1,2</sup>	444	6
Non-violation	6,590	92
Indeterminant <sup>3</sup>	166	2
Total	7,200	100
<b>Freshwater beaches</b>		
Concentration	#	%
Violation <sup>1,2</sup>	336	6
Non-violation	4,611	82
Indeterminant <sup>3</sup>	704	12
Total	5,651	100

1. For marine beaches, Enterococcus is the indicator species. A sample is said to be in violation if the number of colony forming units (CFU) / 100 ml is more than 104 for a single sample or more than 35 for the average of 5 samples over a 30-day period. For freshwater beaches, either Enterococcus or *E. coli* can be used as indicator species. For Enterococcus, a sample is said to be in violation if the number of CFU / 100 ml is more than 61 for a single sample or more than 33 for the average of 5 samples over a 30-day period. For *E. coli*, a sample is said to be in violation if the number of CFU / 100 ml is more than 235 for a single sample or more than 126 for the average of 5 samples over a 30-day period.
2. These numbers are an underestimate of the number of samples that had the potential for bacterial contamination because many samples used an indicator for which there are no current guidelines or failed to report an indicator or indicator level (see number in the indeterminant category).
3. Indeterminant means that an indicator other than those recommended by current guidelines was used, no indicator was reported, or no level was reported.

**Table 13:** The number of beaches in which at least one measured Enterococcus concentration (marine beaches) or at least one Enterococcus or *E. coli* concentration (freshwater beaches) exceeded their respective water quality criteria at public bathing beaches in Massachusetts in 2001.

	# beaches with at least one violation	Total # beaches	%
<b>Marine beaches</b>	158	448	35
<b>Freshwater beaches</b>	130	431	30

**Table 14:** The number of violations at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001, grouped by indicator species.

<b>Marine beaches</b>			
Indicator	Total # samples collected	Total # samples exceeding criterion	% samples exceeding criterion
Enterococcus	7,081	444	6

<b>Freshwater beaches</b>			
Indicator	Total # samples collected	Total # samples exceeding criterion	% samples exceeding criterion
Enterococcus	1,211	203	17
E. coli	3,822	133	3
Fecal coliform	173	N/A	N/A
Total coliform	360	N/A	N/A
Fecal streptococcus	14	N/A	N/A
Not indicated	71	N/A	N/A
Total	5,651	336	6

**Table 15:** The number of violations and postings at marine and freshwater public and semi-public bathing beaches in Massachusetts in 2001.

<b>Marine beaches</b>	
Violations, total (Enterococcus)	444
Postings, total	153
Postings, Enterococcus	146
Postings, Preemptive	3
Postings, Rainfall	4
% of violations that resulted in postings	33
<b>Freshwater beaches</b>	
Violations, total	336
Violations, Enterococcus	203
Violations, E. coli	133
Postings, total	136
Postings, Enterococcus	55
Postings, E. coli	34
Postings, Preemptive	3
Postings, Rainfall	44
% of violations that resulted in postings (Enterococcus)	27
% of violations that resulted in postings (E. coli)	26
% of violations that resulted in postings (overall)	40

**Table 16:** Water quality data for marine public and semi-public bathing beaches in Massachusetts in 2001.

Town	Beach Name	Beach Type	Testing Frequency	Indicator	# Tests	# Violations	Range of Violations (CFU/100 ml)	Range of Non-violations (CFU/100 ml)
